

Forecasting Solutions To Problems From Chapter 2

- 2.1 Trend
 Seasonality
 Cycles
 Randomness
- 2.2 Cycles have repeating patterns that vary in length and magnitude.
- 2.3 a) Time Series
 b) Regression or Causal Model
 c) Delphi Method
- 2.4 Marketing: New sales and existing sales forecasts. Causal models relating advertising to sales
- Accounting Interest rate forecasts; cost components, bad debts.
- Finance: Changes in stock market, forecast return on investment return from specific projects.
- Production: Forecast product demand (aggregate and individual), availability of resources, labor.
- 2.5 a) Aggregate forecasts deal with item groups or families.
- b) Short term forecasts are generally next day or month; Long term forecasts may be for many months or years into the future.
- c) Causal models are based on relationship between predictor variables and other variables. Naive models are based on the past history of series only
- 2.6 The Delphi Method is a technique for achieving convergence of group opinion. The method has several potential advantages over the Jury of Executive Opinion method depending upon how that method is implemented. If the executives are allowed to reach a consensus as a group, strong personalities may dominate. If the executives are interviewed, the biases of the interviewer could affect the results.

- 2.7 Some of the issues that a graduating senior might want to consider when choosing a college to attend include: a) how well have graduates fared on the job market, b) what are the student attrition rates, c) what will the costs of the college education be and d) what part-time job opportunities might be available in the region. Sources of data might be college catalogues, surveys on salaries of graduating seniors, surveys on numbers of graduating seniors going on to graduate or professional schools, etc.
- 2.8 The manager should have been prepared for the consequences of forecast error.
- 2.9 It is unlikely that such long term forecasts are accurate.
- 2.10 This type of criteria would be closest to MAPE, since the errors measured are relative not absolute. It makes more sense to use a relative measure of error in golf. For example, an error of 10 yards for a 200 yard shot would be fine for most golfers, but a similar error for a 20 yard shot would not.
- 2.11 a) $(26)(.1) + (21)(.1) + (38)(.2) + (32)(.2) + (41)(.4) = 35.1$
 b) $(23)(.1) + (28)(.1) + (33)(.2) + (26)(.2) + (21)(.4) = 25.3$
- 2.12 a) and b)

	<u>Forecast</u>	<u>Period</u>	<u>Actual</u>	<u>e_t</u>
$(86 + 75) / 2 =$	80.5	3	72	+8.5
$(75 + 72) / 2 =$	73.5	4	83	-9.5
etc	77.5	5	132	-54.5
	107.5	6	65	42.5
	98.5	7	110	-11.5
	87.5	8	90	-2.5
	100.0	9	67	+33.0
	78.5	10	92	-13.5
	79.5	11	98	-18.5
	95.0	12	73	+22.0

c) $MAD = (216) / 10 = 21.6$
 $MSE = (7175) / 10 = 717.5$

$$MAPE = 100 \left(\frac{1}{n} \sum \left| \frac{e_t}{D_t} \right| \right) = 25.61$$

2.13	<u>Fcst 1</u>	<u>Fcst 2</u>	<u>Demand</u>	<u>Err 1</u>	<u>Err 2</u>	<u>Er1^2</u>	<u>Er2^2</u>	<u> Err1 </u>
	223	210	256	33	46	1089	2116	33
	289	320	340	51	20	2601	400	51
	430	390	375	-55	-15	3025	225	55
	134	112	110	-24	-2	576	4	24
	190	150	225	35	75	1225	5625	35
	550	490	525	-25	35	625	1225	25
						1523.5	1599.166	37.16666
						(MSE1)	(MSE2)	(MAD1)

	<u> Err2 </u>	<u> e1/D *100</u>	<u> e2/D *100</u>
	46	12.89062	17.96875
	20	15.0000	5.88253
	15	14.66667	4.00000
	2	21.81818	1.81818
	75	15.55556	33.33333
	35	4.761905	6.66667
	32.16666	14.11549	11.61155
	(MAD2)	(MAPE1)	(MAPE2)

2.14 It means that $E(e_i) \neq 0$. This will show up by considering

$$\sum_{i=1}^n e_i$$

A bias is indicated when this sum deviates too far from zero.

2.15 Using the MAD: $1.25 \text{ MAD} = (1.25)(21.6) = 27.0$
 (Using s , the sample standard deviation, one obtains 28.23)

2.16 MA (3) forecast: 258.33
 MA (6) forecast: 249.33
 MA (12) forecast: 205.33

2.17, 2.18, and 2.19.

<u>Month</u>	<u>One-step-ahead</u>	<u>Two-step-ahead</u>	<u>Demand</u>	<u>e₁</u>	<u>e₂</u>
	<u>Forecast</u>	<u>Forecast</u>			
July	205.50	149.75	223	-17.50	-73.25
August	225.25	205.50	286	-60.75	-80.50
September	241.50	225.25	212	29.50	13.25
October	250.25	241.50	275	-24.75	-33.50
November	249.00	250.25	188	61.00	62.25
December	240.25	249.00	312	-71.75	-63.00
MAD =				44.2	54.3

The one step ahead forecasts gave better results (and should have according to the theory).

2.20

<u>Month</u>	<u>Demand</u>	<u>MA (3)</u>	<u>MA (6)</u>
July	223	226.00	161.33
August	286	226.67	183.67
September	212	263.00	221.83
October	275	240.33	233.17
November	188	257.67	242.17
December	312	225.00	244.00

MA (6) Forecasts exhibit less variation from period to period.

2.21 An MA(1) forecast means that the forecast for next period is simply the current period's demand.

<u>Month</u>	<u>Demand</u>	<u>MA(4)</u>	<u>MA(1)</u>	<u>Error</u>
July	223	205.50	280	57
August	286	225.25	223	-63
September	212	241.50	286	74
October	275	250.25	212	-63
November	188	249.00	275	87
December	312	240.25	188	-124

MAD = 78.0
(Much worse than MA(4))

2.22 $F_t = \alpha D_{t-1} + (1-\alpha)F_{t-1}$

a) $F_{Feb} = (.15)(23.3) + (.85)(25) = 24.745$

$F_{March} = (.15)(72.3) + (.85)(24.745) = 31.88$

$F_{Apr} = (.15)(30.3) + (.85)(31.88) = 31.64$

$F_{May} = (.15)(15.5) + (.85)(31.63) = 29.22$

b) $F_{Feb} = (.40)(23.3) + (.60)(25) = 24.32$

$F_{March} = 43.47$

$F_{Apr} = 38.20$

$F_{May} = 29.12$

c) Compute MSE for February through April:

Month	Error (a) ($\alpha = .15$)	Error (b) ($\alpha = .40$)
Feb	47.45	47.88
Mar	1.56	13.17
Apr	16.13	22.70
MSE =	838.04	993.74

$\alpha = .15$ gave a better forecast

2.23 Small α implies little weight is given to the current forecast and virtually all weight is given to past history of demand. This means that the forecast will be stable but not responsive.

Large α implies that a great deal of weight is applied to current observation of demand. This means that the forecast will adjust quickly to changes in the demand pattern but will vary considerably from period to period.

2.24 a)

<u>Week</u>	<u>MA (3) Forecast</u>
4	17.67
5	20.33
6	28.67
7	22.67
8	21.67

b) and c

<u>Week</u>	<u>ES (.15)</u>	<u>Demand</u>	<u>MA (3)</u>	<u> err </u>	<u> err </u>
4	17.67	22	17.67	4.33	4.33
5	18.32	34	20.33	15.68	13.67
6	20.67	12	28.67	8.67	16.67
7	19.37	19	22.67	0.37	3.67
8	19.32	23	21.67	3.68	1.33
				6.547540	7.934
				MAD-ES	MAD-MA

Based on these results, ES(.15) had a lower MAD over the five weeks

d) It is the same as the exponential smoothing forecast made in week 6 for the demand in week 7, which is 19.37 from part c).

2.25 a) $\alpha = \frac{2}{N+1} \propto \alpha = \frac{2}{7} = .286$

b) $N = \frac{2-\alpha}{\alpha} \propto N = \frac{2-.05}{.05} = 39$

c) From Appendix 2-A $\sigma_e^2 = \frac{\sigma^2}{2-\alpha} = 1.1\sigma^2$

Hence $\frac{2}{2-\alpha} = 1.1$ Solving gives $\alpha = .1818$

2.26 It is the same as the one step ahead forecast made at the end of March which is 31.64.

2.27 The average demand from Jan to June is 161.33. Assume this is the forecast for July.

a)

<u>Month</u>	<u>Forecast</u>
Aug	173.7 [.2(223) + (.8)(161.33)]
Sept	196.2 etc.
Oct	199.4
Nov	214.5
Dec	209.2

b)

<u>Month</u>	<u>Demand</u>	<u>ES(.2)</u>	<u>(Error)</u>	<u>MA(6)</u>	<u>(Error)</u>
Aug	286	173.7	112.3	183.7	102.3
Sept	212	196.2	15.8	221.8	9.8
Oct	275	199.4	75.6	233.2	41.8
Nov	188	214.5	26.5	242.2	54.2
Dec	312	209.2	102.8	244	68.0
		MAD	66.6		55.2

MA(6) gave more accurate forecasts.

c) For $\alpha = .2$ the consistent value of N is $(2-\alpha)/\alpha = 9$. Hence MA(6) will be somewhat more responsive. Also the ES method may suffer from not being able to flush out "bad" data in the past.

- a) “Eyeball” estimates: slope = $2750/6 = 458.33$, intercept = -500 .
- b) Regression solution obtained is

$$S_{xy} = (6)(28,594) - (21)(5667) = 52,557$$

$$S_{xx} = (6)(91) - (21)^2 = 105$$

$$b = \frac{S_{xy}}{S_{xx}} = \frac{52,577}{105} = 500.54$$

$$a = \bar{D} - b(n+1)/2 = -.807.4$$

- c) Regression equation

$$\bar{D}_t = -807.4 + (500.54)t$$

<u>Month</u>	<u>Forecasted Usage</u>
July (t = 7)	2696
Aug (t = 8)	3197
Sept (t = 9)	3698
Oct (t = 10)	4198
Nov (t = 11)	4699
Dec (t = 12)	5199

- d) One would think that peak usage would be in the summer months and the increasing trend would not continue indefinitely.

2.29 a)

<u>Month</u>	<u>Forecast</u>	<u>Month</u>	<u>Forecast</u>
Jan	5700	July	8703
Feb	6200	Aug	9203
Mar	6700	Sept	9704
Apr	7201	Oct	10,204
May	7702	Nov	10,705
June	8202	Dec	11,206

(note that these are obtained from the regression equation

$$\hat{D}_t = 807.4 + 500.54 t \text{ with } t = 13, 14, \dots)$$

The total usage is obtained by summing forecasted monthly usage.

$$\text{Total forecasted usage for 1994} = 101,431$$

b) Moving average forecast made in June = 944.5/mo.

Since this moving average is used for both one-step-ahead and multiple-step-ahead forecasts, the total forecast for 1994 is $(944.5)(12) = 11,334.$

The monthly average is about 1200 based on a usage graph of this shape. This graph assumes peak usage in summer months. The yearly usage is $(1200)(12) = 14,400$ which is much closer to (b), since the moving average method does not project trend indefinitely.

2.30 From the solution of problem 24,

a) slope = 500.54
 value of regression in June = $-807.4 + (500.54)(6) = 2196$

$$S_0 = 2196 \quad \alpha = .15$$

$$G_0 = 500.54 \quad \beta = .10$$

$$S_1 = \alpha D_1 + (1-\alpha)(S_0 + G_0)$$

$$= (.15)(2150) + (.85)(2196 + 500.54)$$

$$= 2615$$

$$G_1 = (.1)[2615 - 2196] + (.9)(500.54) = 492.4$$

$$S_2 = (.15)(2660) + (.85)(2615 + 492.4) = 3040$$

$$G_2 = .1 [3040 - 2615] + (.9) (492.4) = 485.7$$

b) One-step-ahead forecast made in Aug. for Sept. is
 $S_2 + G_2 = 3525.7$

Two-step-ahead forecast made in Aug for Oct is
 $S_2 + G_2 = 3040 + 2(485.7) = 4011.4$

c) $S_1 + 5(G_1) = 2615 + 5(492.4) = 5077.$

2.31 This observation would lower future forecasts. Since it is probably an "outlier" (non-representative observation) one should not include it in forecast calculations.

2.32 Both regression and Holt's method are based on the assumption of constant linear trend. It is likely in many cases that the trend will not continue indefinitely or that the observed trend is just part of a cycle. If that were the case, significant forecast errors could result.

2.33

Month	Yr 1	Yr 2	Dem1/Mean	Dem2/Mean	Avg (factor) "
1	12	16	0.20	0.27	0.24
2	18	14	0.31	0.24	0.27
3	36	46	0.61	0.78	0.70
4	53	48	0.90	0.81	0.86
5	79	88	1.34	1.49	1.42
6	134	160	2.27	2.71	2.49
7	112	130	1.90	2.20	2.05
8	90	83	1.53	1.41	1.47
9	66	52	1.12	0.88	1.00
10	45	49	0.76	0.83	0.80

Chapter 02 - Forecasting

11	23	14	0.39	0.24	0.31
12	21	26	0.36	0.44	0.40
Totals	689	726			12

We used the Quick and Dirty Method here. The average demand for the two years was $(689 + 726)/2 = 707.5$.

2.34 a)

<u>Quarter</u>	(1)		(2)		<u>Ratio</u> <u>(1) / (2)</u>
	<u>Demand</u>	<u>MA</u>	<u>Centered MA</u>	<u>Centered MA</u> <u>on periods</u>	
1	12			42.440	0.2828
2	25		41.25	42.440	0.5891
3	76		42.25	41.750	1.8204
4	52	41.25	44.00	43.125	1.2058
5	16	42.25	42.75	43.375	0.3689
6	32	44.00	45.25	44.000	0.7272
7	71	42.75	44.75	45.000	1.5778
8	62	45.25	48.00	46.375	1.3369
9	14	44.75	51.25	49.625	0.2821
10	45	48.00	47.50	49.375	0.9114
11	84	51.25		49.500	1.6970
12	47	47.50		49.500	0.9494

The four seasonal factors are obtained by averaging the appropriate quarters (1, 5, 9 for first; 2, 6, 10 for the second, etc.)

One obtains the following seasonal factors

0.3112
0.7458
1.6984
1.1641

The sum is 3.9163. Norming the factors by multiplying each by

$$\frac{4}{3,9163} = 1.0214$$

we finally obtain the factors:

0.318
 0.758
 1.735
 1.189

b)

<u>Quarter</u>	<u>Demand</u>	<u>Factor</u>	<u>Deseasonalized Series</u>
1	12	0.318	37.74
2	25	0.758	32.98
3	76	1.735	43.80
4	52	1.189	43.73
5	16	0.318	50.31
6	32	0.758	42.22
7	71	1.735	40.92
8	62	1.189	52.14
9	14	0.318	44.03
10	45	0.758	59.37
11	84	1.735	48.41
12	47	1.189	39.53

c) 47.40

d) Must "re-seasonalize" the forecast from part (c)
 $(47.40)(.318) = 15.07$

2.35 a) $V_1 = (16 + 32 + 71 + 62)/4 = 45.25$
 $V_2 = (14 + 45 + 84 + 47)/4 = 47.5$

1. $G_0 = (V_2 - V_1)/N = 0.5625$

2. $S_0 = V_2 + G_0 (N-1/2) = 47.5 + (0.5625)(3/2) = 48.34$

3. $c_t = \frac{D_t}{V_i[N + 1/2 - j]G_0} \quad -2N+1 \leq t \leq 0$

$$c_{-7} = \frac{16}{45.25 - (5/2 - 1)(.56)} = 0.36$$

$$c_{-6} = \frac{32}{45.25 - (5/2 - 2)(.56)} = 0.71$$

$$c_{-5} = \frac{71}{43.25 - (5/2 - 3)(.56)} = 1.56$$

$$c_{-4} = \frac{62}{45.25 - (5/2 - 4)(.56)} = 1.35$$

$$c_{-3} = \frac{14}{47.5 - (5/2 - 1)(.56)} = 0.30$$

$$c_{-2} = \frac{45}{47.5 - (5/2 - 2)(.56)} = 0.95$$

$$c_{-1} = \frac{84}{47.5 - (5/2 - 3)(.56)} = 1.76$$

$$c_0 = \frac{47}{47.5 - (5/2 - 4)(.56)} = 0.97$$

$$(c_7 + c_3)/2 = .33$$

$$(c_6 + c_2)/2 = .83$$

$$(c_5 + c_1)/2 = 1.66$$

$$(c_4 + c_0)/2 = \underline{1.16}$$

$$\text{Sum} = 3.98$$

$$\text{Norming factor} = 4/3.9 = 1.01$$

Hence the initial seasonal factors are:

$$c_{-3} = .33 \quad c_{-1} = 1.67$$

$$c_{-2} = .83 \quad c_0 = 1.17$$

b) $\alpha = 0.2, \beta = 0.15, \gamma = 0.1, D_1 = 18$

$$S_1 = \alpha(D_1/c_{-3}) + (1-\alpha)(S_0 + G_0) = 0.2(18/0.33) + 0.8(48.34 + 0.56) = 50.03$$

$$G_1 = \gamma(S_1 - S_0) + (1 - \gamma)G_0 = 0.1(50.03 - 48.34) + 0.9(0.56) = 0.70$$

$$c_1 = \beta(D_1/S_1) + (1-\beta)c_3 = 0.15(18/50.03) + 0.85(0.33)$$

$$= .3345$$

c) Forecasts for 2nd, 3rd and 4th quarters of 1993

$$F_{1,2} = [S_1 + G_1]c_2 = (50 + .70)0.83 = 42.08$$

$$F_{1,3} = [S_1 + 2G_1]c_3 = (50 + 2(.70))1.67 = 85.84$$

$$F_{1,4} = [S_1 + 3G_1]c_4 = (50 + 3(.70))1.17 = 60.96$$

2.36

Period	D_t	Forecast from 30(d)	$ e_t $	Forecast from 31(c)	$ e_t $
1					
2	51	35.8	15.2	42.08	8.92
3	86	82.4	3.6	85.84	0.16
4	<u>66</u>	56.5	<u>9.5</u>	60.96	<u>5.04</u>

$$MAD = 9.43 \quad MAD = 4.71$$

$$MSE = 111.42 \quad MSE = 35.00$$

Hence we conclude that Winter's method is more accurate.

2.37

$$S_1 = 50.03 \quad \alpha = 0.2 \quad \beta = 0.15 \quad \gamma = 0.1$$

$$G_1 = 0.67$$

$$D_1 = 18$$

$$D_2 = 51$$

$$D_3 = 85$$

$$D_4 = 66$$

$$S_2 = 0.2(51/0.83) + 0.8(50.03 + 0.70) = 52.87$$

$$G_2 = 0.1(52.87 - 50.03) + 0.9(0.70) = 0.914$$

$$S_3 = 0.2(86/1.67) + 0.8(52.87 + 0.914) = 53.33$$

$$G_3 = 0.1(53.33 - 52.85) + 0.9(0.885) = 0.8445$$

$$S_4 = 0.2(66/1.17) + 0.8(53.33 + 0.8445) = 54.62$$

$$G_4 = 0.1(54.62 - 53.33) + 0.9(0.8445) = 0.8891$$

$$c_1 = (.15)[18/50] + (0.85)(.33) = .3345 \approx .34$$

$$c_2 = (.15)[51/52.85] + 0.85(0.83) = .8502 \approx .85$$

$$c_3 = (.15)(86/53.29) + 0.85(1.67) = 1.6616 \approx 1.66$$

$$c_4 = (.15)(66/54.59) + 0.85(1.17) = 1.1758 \approx 1.18$$

The sum of the factors is 4.02. Norming each of the factors by multiplying by $4/4.02 = .995$ gives the final factors as:

$$c_1 = .34$$

$$\begin{aligned}c_2 &= .84 \\c_3 &= 1.65 \\c_4 &= 1.17\end{aligned}$$

The forecasts for all of 1995 made at the end of 1993 are:

$$F_{4,9} = [S_4 + 5G_4]c_1 = [54.62 + 5(0.89)]0.34 = 20.08$$

$$F_{4,10} = [S_4 + 6G_4]c_2 = [54.62 + 6(0.89)]0.84 = 50.37$$

$$F_{4,11} = [S_4 + 7G_4]c_3 = [54.62 + 7(0.89)]1.65 = 100.40$$

$$F_{4,12} = [S_4 + 8G_4]c_4 = [54.62 + 8(0.89)]1.17 = 72.24$$

2.42. ARIMA(2,1,1) means 2 autoregressive terms, one level of differencing, and 1 moving average term. The model may be written $u_t = a_0 + a_1u_{t-1} + a_2u_{t-2} + \varepsilon_t - b_1\varepsilon_{t-1}$

where $u_t = D_t - D_{t-1}$. Since $u_t = (1 - B)D_t$, we have

$$\text{a) } (1 - B)D_t = a_0 + (a_1B + a_2B^2)(1 - B)D_t + (1 - b_1B)\varepsilon_t$$

$$\text{b) } \nabla D_t = a_0 + (a_1B + a_2B^2)\nabla D_t + (1 - b_1B)\varepsilon_t$$

$$\text{c) } D_t - D_{t-1} = a_0 + a_1(D_{t-1} - D_{t-2}) + a_2(D_{t-2} - D_{t-3}) + \varepsilon_t - b_1\varepsilon_{t-1} \quad \text{or}$$

$$D_t = a_0 + (1 + a_1)D_{t-1} - a_1D_{t-2} + a_2(D_{t-2} - D_{t-3}) + \varepsilon_t - b_1\varepsilon_{t-1}$$

2.43. ARIMA(0,2,2) means no autoregressive terms, 2 levels of differencing, and 2 moving average terms. The model may be written as

$$w_t = b_0 + \varepsilon_t - b_1\varepsilon_{t-1} - b_2\varepsilon_{t-2}$$

Where $w_t = u_t - u_{t-1}$ and $u_t = D_t - D_{t-1}$. Using backshift notation, we may also write

$w_t = (1 - B)^2 D_t$, so that we have for part a)

$$\text{a) } (1 - B)^2 D_t = b_0 + (1 - b_1B - b_2B^2)\varepsilon_t$$

$$\text{b) } \nabla^2 D_t = b_0 + (1 - b_1B - b_2B^2)\varepsilon_t$$

$$\text{c) } D_t - 2D_{t-1} + D_{t-2} = b_0 + \varepsilon_t - b_1\varepsilon_{t-1} - b_2\varepsilon_{t-2} \quad \text{or} \quad D_t = 2D_{t-1} - D_{t-2} + b_0 + \varepsilon_t - b_1\varepsilon_{t-1} - b_2\varepsilon_{t-2}$$

2.44. The ARMA(1,1) model may be written $D_t = a_0 + a_1D_{t-1} - b_1\varepsilon_{t-1} + \varepsilon_t$. If we substitute for D_{t-1}, D_{t-2}, \dots one can easily see this reduces to a polynomial in $(\varepsilon_t, \varepsilon_{t-1}, \dots)$ and if we substitute for $\varepsilon_t, \varepsilon_{t-1}, \dots$ we see that this reduces to a polynomial in D_{t-1}, D_{t-2}, \dots .

2.45 a) $1400 - 1200 = 200$
 $200/5 = 40$ Change = -40 (He should decrease the forecast by 40.)

b) $(0.2)(0.8)^4 = 0.08192$
 $200(0.08192) = 16.384$ Change = -16.384 (He should decrease the forecast by 16.384)

2.46 From Example 2.2 we have the following:

<u>Quarter</u>	<u>Failures</u>	<u>Forecast (ES(.1))</u>	<u>Observed Error (e_t)</u>
2	250	200	-50
3	175	205	+30
4	186	202	+16
5	225	201	-24
6	285	203	-82
7	305	211	-94
8	190	220	+30

Using $MAD_t = \alpha |e_t| + (1 - \alpha)MAD_{t-1}$, we would obtain the following values:

$MAD_1 = 50$ (given)

$MAD_2 = (.1)(50) + (.9)(50) = 50.0$

$MAD_3 = (.1)(30) + (.9)(50) = 48.0$

$MAD_4 = (.1)(16) + (.9)(48) = 44.8$

$MAD_5 = (.1)(24) + (.9)(44.8) = 42.7$

$MAD_6 = (.1)(82) + (.9)(42.7) = 46.6$

$MAD_7 = (.1)(94) + (.9)(46.6) = 51.3$

$MAD_8 = (.1)(30) + (.9)(51.3) = 49.2$

The MAD obtained from direct computation is 46.6, so this method gives a pretty good approximation after eight periods. It has the important advantage of not requiring the user to save past error values in computing the MAD.

2.47 $c_1 = 0.7$
 $c_2 = 0.8$
 $c_3 = 1.0$
 $c_4 = 1.5$

				79.18	11616.03	36.41
				MAD	MSE	MAPE

The error turns out to be a declining function of α for this data. Hence, $\alpha = 1$ gives the lowest error.

2.51 a)

Year	(Y _i) Sales (\$100,000)	(X _i) Births Preceding Year
1		
2	6.4	2.9
3	8.3	3.4
4	8.8	3.5
5	5.1	3.1
6	9.2	3.8
7	7.3	2.8
8	12.5	4.2

$$\text{Obtain } \sum X_i = 23.7, \sum Y_i = 57.6, \sum X_i Y_i = 201.29$$

$$\sum X_i^2 = 81.75, \sum Y_i^2 = 507.48$$

$$S_{xx} = 10.56 \quad S_{xy} = 43.91$$

$$b = \frac{S_{xy}}{S_{xx}} = 4.158$$

$$a = \bar{y} - b \bar{x} = -5.8$$

Hence $Y_t = -5.8 + 4.158X_{t-1}$ is the resulting regression equation.

b) $Y_{10} = -5.8 + (4.158)(3.3) = 7.9214$ (that is, \$792,140)

c)

Year	US Births (in 1,000,000) (X_i)	Forecasted Births Using ES (.15)
	1	2.9
2	3.4	
3	3.5	
4	3.1	
5	3.8	3.2
6	2.8	3.3
7	4.2	3.2
8	3.7	3.4
9		3.4
10		3.4

Hence, forecasted births for years 9 and 10 is 3.4 million.

d) $Y_t = -5.8 + 4.158 X_{t-1}$

$X_{t-1} = 3.4$ million in years 8 and 9.

Substituting gives $Y_t = -5.8 + (4.158)(3.4) = 8.3372$ for sales in each of years 9 and 10. Hence the forecast of total aggregate sales in these years is $(8.3372)(2) = 16.6744$ or \$1,667,440.

2.52 a)

Month	Ice cream Sales	Park Attendees
	1	325
2	335	976
3	172	440
4	645	1823
5	770	1885
6	950	2436

Month	X_i Ice Cream Sales	Y_i Park Attendees	$X_i Y_i$
	1	325	
2	335	976	670
3	172	440	516
4	645	1823	2580
5	770	1885	3850
6	950	2436	5700

Sum	= 21	3197.	13641
Avg	= 3.5	532.8	

$S_{xx} = 105$
 $S_{xy} = 14709$

$$b = S_{xy}/S_{xx} = 140.1$$

$$a = \bar{Y} - b \bar{X} = 42.5$$

$$Y_{30} = 42.5 + (30)(140) = \$4245.1$$

We would not be very confident about this answer since it assumes the trend observed over the first six months continues into month 30 which is very unlikely.

b)

	X_i Park attendees	Y_i Ice Cream Sales	$X_i Y_i$
	880	325	286000
	976	335	326960
	440	172	75680
	1823	645	1175835
	1885	770	1451450
	<u>2436</u>	<u>950</u>	<u>2314200</u>
Sum =	8440	3197	5630125
Avg =	1406.666	532.8333	

$$S_{xx} = 17,153,756$$

$$S_{xy} = 6,798,070$$

$$b = S_{xy}/S_{xx} = 0.396302$$

$$a = \bar{Y} - b \bar{X} = 24.6316$$

Hence the resulting regression equation is:

$$Y_i = -24.63 + 0.4X_i$$

Reading the values from the curve:

$$X_{12} \approx 5100$$

$$X_{13} \approx 5350$$

$$X_{14} \approx 5600$$

$$X_{15} \approx 5800$$

$$X_{16} \approx 5900$$

$$X_{17} \approx 5950$$

$$X_{18} \approx 5980$$

Using the regression equation $Y_i = -24.63 + 0.4X_i$ derived in part (b) we obtain the ice cream sales predictions below.

<u>Month</u>	<u>Attendees</u>	<u>Predicted Ice Cream Sales</u>
12	5100	2015.37
13	5350	2115.37
14	5600	2215.37
15	5800	2295.37
16	5900	2335.37
17	5950	2355.37
18	5980	2367.37

2.53 The method assumes that the "best" α based on a past sequence of specific demands will be the "best" α for future demands, which may not be true. Furthermore, the best value of the smoothing constant based on a retrospective fit of the data may be either larger or smaller than is desirable on the basis of stability and responsiveness of forecasts.

2.54

Year	Demand	S sub t	G sub t	Forecast	alpha	beta	error	error ²
		0	8		0.2	0.2		
1981	0.2	6.44	7.69	8.00			7.80	60.84
1982	4.3	12.16	7.29	14.13			9.83	96.59
1983	8.8	17.33	6.87	19.46			10.66	113.58

							14.05	308.78
							MAD	MSE

The forecast error appears to decrease with decreasing values of α and β . That is, $\alpha = \beta = 0$ appears to give the lowest value of the forecast error.

2.55

a) We are given in problem 22 that the forecast for January was 25.

Hence $e_1 = 25 - 23.3 = 1.7 = E_1$ and $M_1 = |e_1| = 1.7$ as well. Hence $\alpha_1 = 1$.

$$F_{\text{Feb}} = (1)(23.3) + (0)(25) = 23.3$$

$$e_2 = 23.3 - 72.2 = -48.9$$

$$E_2 = (.1)(-48.9)(.9)(1.7) = -3.36$$

$$M_2 = (.1)(48.9) + (.9)(1.7) = 6.42$$

$$\alpha_2 = 3.36/6.42 = .5234$$

$$F_{\text{March}} = (.5234)(72.2) + (.4766)(23.3) = 48.73$$

$$e_3 = 48.73 - 30.3 = 18.43$$

$$E_3 = (.1)(18.43) + (.9)(-3.36) = -3.024$$

$$M_3 = (.1)(18.43) + (.9)(6.42) = 7.621$$

$$\alpha_3 = 3.024/7.621 = .396 \sim .40$$

$$F_{\text{Apr}} = (.40)(30.3) + (.60)(48.73) = 41.358$$

Comparison of Methods

<u>Month</u>	<u>Demand</u>	<u>ES(.15)</u>	<u> Error </u>	<u>Trigg-Leach</u>	<u> Error </u>
Feb	72.2	24.745	47.5	23.3	48.9
March	30.3	31.87	1.6	48.7	18.4
April	15.5	31.63	16.1	41.4	25.9

Obviously Trigg-Leach performed much worse for this 3-month period than did ES(.12). (The respective MAD's are 21.7 for ES and 31.1 for Trigg-Leach.)

- b) Consider only the period July to December as in problem 36. As in part (a) $\alpha_7 = 1$. Use $E_6 = 567.1 - 480 = 87$.

$$F_7 = 480$$

$$e_7 = 480 - 500 = -20$$

$$E_7 = (.2)(-20) + (.8)(87) = 65.6$$

$$M_7 = (.2)(20) + (.8)(87) = 73.6$$

$$\alpha_7 = 65.6/73.6 = .89$$

$$F_8 = (.89)(500) + (.11)(480) = 498$$

$$e_8 = 498 - 950 = -452$$

$$E_8 = (.2)(-452) + (.8)(65.6) = -37.9$$

$$M_8 = (.2)(452) + (.8)(73.6) = 149.3$$

$$\alpha_8 = 37.9/149.3 = .25$$

$$F_9 = (.25)(950) + (.75)(498) = 611$$

$$e_9 = 611 - 350 = 261$$

$$E_9 = (.2)(261) + (.8)(-37.9) = 21.9$$

$$M_9 = (.2)(261) + (.8)(149.3) = 171.6$$

$$\alpha_9 = 21.9/171.6 = .13$$

$$F_{10} = (.13)(350) + (.87)(620) = 584.9$$

$$e_{10} = 584.9 - 600 = -15.1$$

$$E_{10} = (.2)(-15.1) + (.8)(21.9) = 14.5$$

$$M_{10} = (.2)(17.8) + (.8)(171.6) = 140.8$$

$$\alpha_{10} = 14.5/140.8 = .10$$

$$F_{11} = (.10)(600) + (.90)(584.9) = 586.4$$

$$e_{11} = 586.4 - 870 = -283.6$$

$$E_{11} = (.2)(-283.6) + (.8)(14.5) = -45.1$$

$$M_{11} = (.2)(283.6) + (.8)(140.8) = 169.4$$

$$\alpha_{11} = 45.1/169.4 = .27$$

$$F_{12} = (.27)(870) + (.73)(586.4) = 663.0$$

Performance Comparison

<u>Month</u>	<u>Demand</u>	<u>Trigg-Leach Forecast</u>	<u> Error </u>
7	500	480	20
8	950	498	452
9	350	611	261
10	600	585	15
11	870	586	284
12	740	663	77

$$\text{MAD} = 185$$

The MAD for ES(.2) from problem 36 was 194.5.
Hence Trigg-Leach was slightly better for this problem.

- c) Trigg-Leach will out-perform simple exponential smoothing when there is a trend in the data or a sudden shift in the series to a new level, since α will be adjusted upward in these cases and the forecast will be more responsive. However, if the changes are due to random fluctuations, as in part (a), Trigg-Leach will give poor performance as the forecast tries to "chase" the series.

2.56 Given information:

$$\alpha = .2, \quad \beta = 0.2, \quad \text{and} \quad \gamma = 0.2$$

$$S_{10} = 120, \quad G_{10} = 14$$

$$c_{10} = 1.2$$

$$c_9 = 1.1$$

$$c_8 = 0.8$$

$$c_7 = 0.9$$

a) $F_{11} = (S_{10} + G_{10})c_7 = (120 + 14)(0.9) = 120.6$

b) $D_{11} = 128$

$$S_{11} = \alpha(D_{11}/c_7) + (1 - \alpha)(S_{10} + G_{10}) = 135.6$$

$$G_{11} = \gamma(S_{11} - S_{10}) + (1 - \gamma)G_{10} = 14.3$$

$$c_{11} = \beta(D_{11}/S_{11}) + (1 - \beta)c_7 = .909$$

$$\sum_{t=8}^{11} C_t = 4.009$$

The factors are normed by multiplying each by $1/4.009 = .9978$
They will not change appreciably.

$$F_{11,13} = (S_{11} + 2G_{11})C_9 = (135.6 + (2)(14.3))1.1 = 180.6$$

2.57 a)

	<u>X_i</u>	<u>Y_i</u>	<u>X_iY_i</u>

60.4 *MAD = 57.1 *MAD =

The moving average and exponential smoothing forecasts based on percentage increases are more accurate than Holt's method.

- c) One would expect that a causal model might be more accurate. Large-scale econometric models for predicting GNP and other fundamental economic time series are common.
